

Question 1.

Given the description of a program in mC as follows:

A program in mC consists of many declarations, which are variable and function declarations.

A variable declaration starts with a type, which is *int* or *float*, then a comma-separated list of identifiers and ends with a semicolon.

A function declaration also start with a type and then an identifier, which is the function name, and then parameter declaration and ends with a body. The parameter declaration starts with a left round bracket '(' and a null-able semicolon-separated list of parameters and ends with a right round bracket ')'. Each parameter always starts with a type and then a comma-separated list of identifier. A body starts with a left curly bracket '{'}, follows by a null-able list of variable declarations or statements and ends with a right curly bracket '{'}}.

There are 3 kinds of statements: assignment, call and return. All statements must end with a semicolon. An assignment statement starts with an identifier, then an equal '=', then an expression. A call starts with an identifier and then follows by a null-able commaseparated list of expressions enclosed by round brackets. A return statement starts with a symbol 'return' and then an expression.

An expression is a construct which is made up of operators and operands. They calculate on their operands and return new value. There are four kinds of infix operators: '+', '-', '*' and '/' where '+' have lower precedence than '-' while '*' and '/' have the highest precedence among these operators. The '+' operator is right associative, '-' is non-associative while '*' and '/' is left-associative. To change the precedence, a sub-expression is enclosed in round brackets. The operands can be an integer literal, float literal, an identifier, a call or a sub-expression.

```
For example,

int a,b,c;

float foo(int a; float c,d) {
    int e;
    e = a + 4;
    c = a * d / 2.0;
    return c + 1;
}

float goo(float a,b) {
    return foo(1,a,b);
}
```

The following tokens can be used for the grammar:

ID (for identifiers), INTLIT (for integer literals), FLOATLIT (for float literals), INT, FLOAT, RETURN, LB (for '{'}), RB (for '}'), SM (for ';'), CM (for ','), EQ (for '='), LP (for '('), RP (for ')'), ADD (for '+'), SUB (for '-'), MUL (for '*'), DIV (for '/').

a. Write the grammar of a program in mC in BNF format.

b. Write a recognizer in ANTLR to detect if a mC program is written correctly or not

prog -> manyDecl
manyDecl -> decl manyDecl | decl
